GMPE residuals using the NGA-East database: accounting for mixed effects

Christine Goulet, PhD
PEER, UC Berkeley
goulet@berkeley.edu

Data and analysis options

- NGA-East v3.0 (August 2012) database
- Used geometric mean of as-is components
- Kept only events recorded at at least 5 stations
- Used limited bandwidth based on filter corners
- Residuals for PGA, 0.2, 0.5, 1.0 and 2.0 sec.
- Multiple variations on limits
 - All Ms and M>4
 - All Rs, R<200, R<1000
 - With and without the Gulf Coast...
- R_{jb} and R_{rup} taken as R_{epi} and R_{hypo}
- V_{s30} set to 760 m/s for computations (USGS site factors applied to HR)
- V_{s30} reported on plots based on
- Measured (~100 sites total)
 - Inferred or estimated (from NGA-East Geotech WG, personal priority selection)

Caveat: Range of data considered for examples exceeds GMPE development limits, presentation for proof of concept only

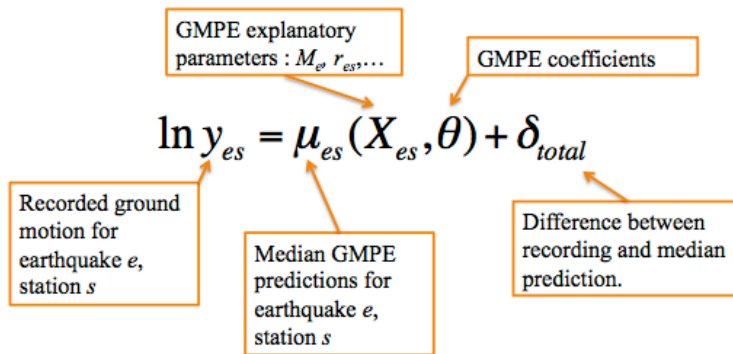

Models considered

- Frankel et al. (1996)
- Toro et al. (1997) modified by Toro (2002)
 - Mid-Continent
 - Gulf Coast
- Silva et al. (2002)
- Campbell (2003)
- Atkinson (2008) as modified by Atkinson & Boore (2011)*
- Atkinson & Boore (2006) as modified by Atkinson & Boore (2011)*
- Somerville et al. (2001)
- Somerville et al. (2009) – Australia, Cratonic
- Pezeshk et al. (2011)

All corrected from hard rock ($V_{s30} \sim 2800$ m/s) to BC boundary ($V_{s30} = 760$ m/s) using USGS site factors (Frankel et al. 1996) except * which include a site effects terms

Residuals analysis

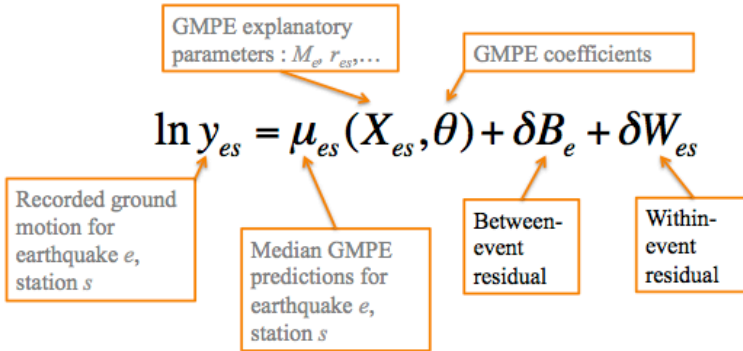

Total residuals

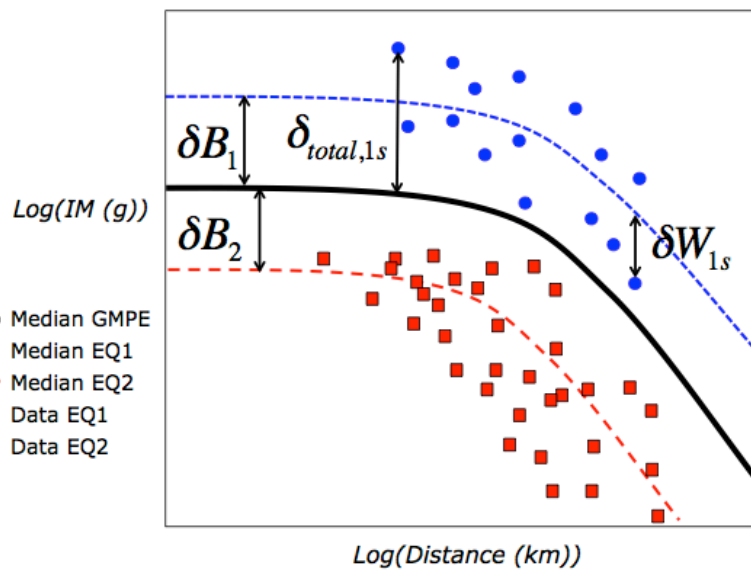

$$\delta_{total} = [\ln y_{es}]_{Rec} - [\ln \mu_{es}]_{GMPE}$$

Residuals analysis - Partitioning

$$\ln y_{es} = \mu_{es}(X_{es}, \theta) + \delta B_e + \delta W_{es}$$

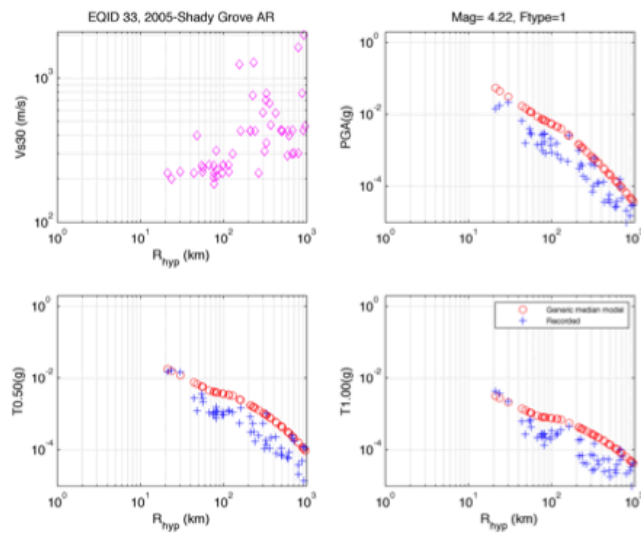

Using residuals to evaluate GMPEs

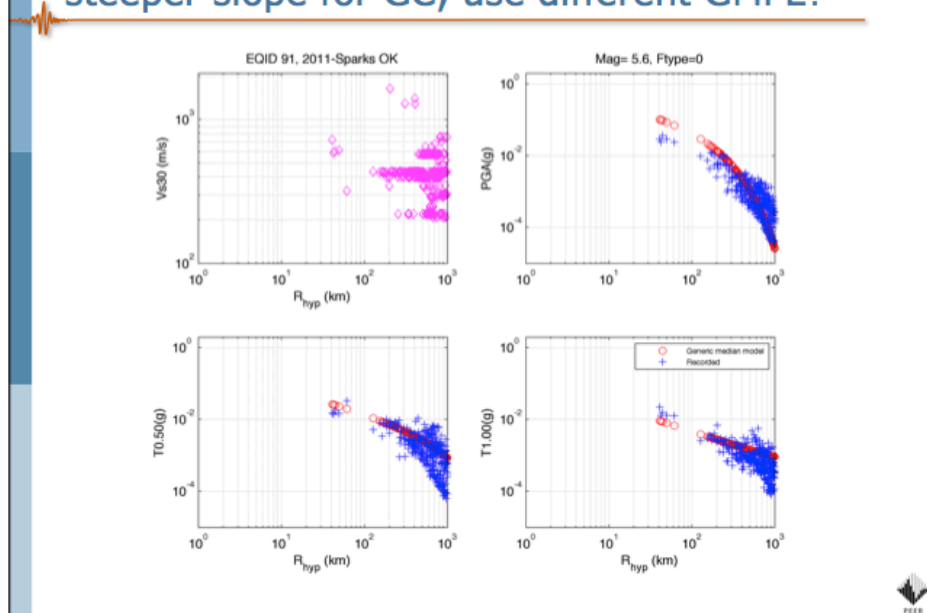

- Total and between-event residuals useful to assess ability of GMPE to model attenuation (data/GMPE slopes similar or not)

Ground motions comparison – examples – reasonable slope match

Ground motions comparison – examples – steeper slope for GC, use different GMPE!

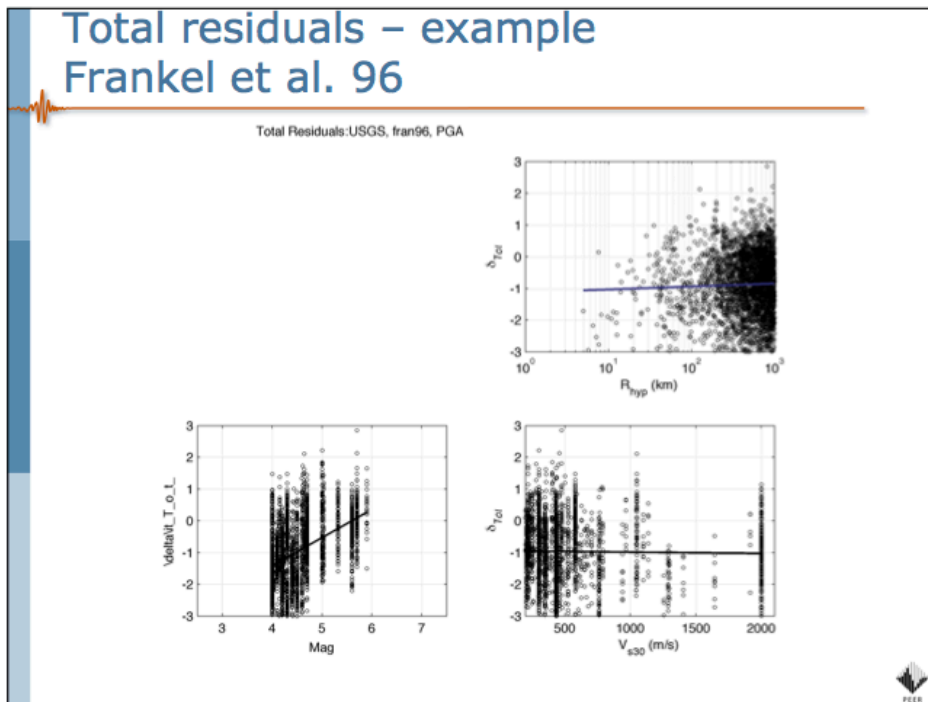

Using residuals to evaluate GMPEs

- Total and between-event residuals useful to assess ability of GMPE to model attenuation (slopes similar or not)
- Total residuals give an idea of the overall misfit
 - Uneven sampling of events: mean should not be zero in general. A few well-recorded events with high or low stress-drop may “pull” the residuals in a given direction
- Separated residuals (within- and between- event)
 - Addresses uneven sampling and correlation in dataset: changes the weighting of data points, not one single event controls the interpretation

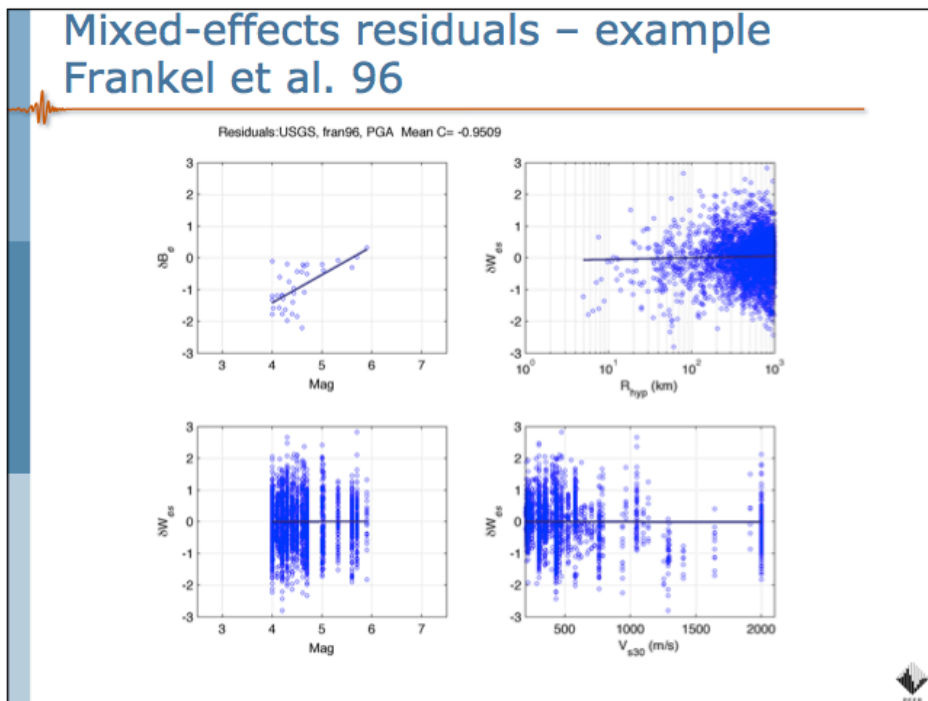

Be careful with trade-offs for correlated data sets (e.g. small events recorded on a given site condition or large events in a specific region)

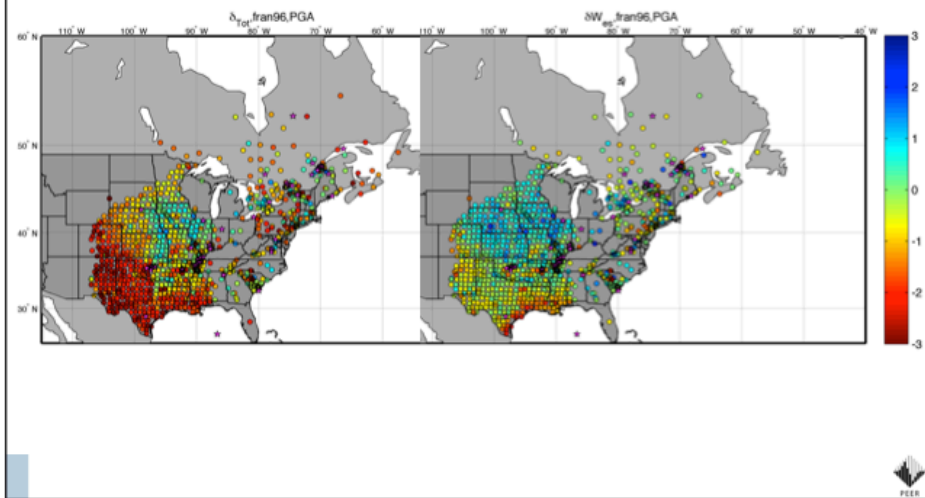

Total residuals – example Frankel et al. 96

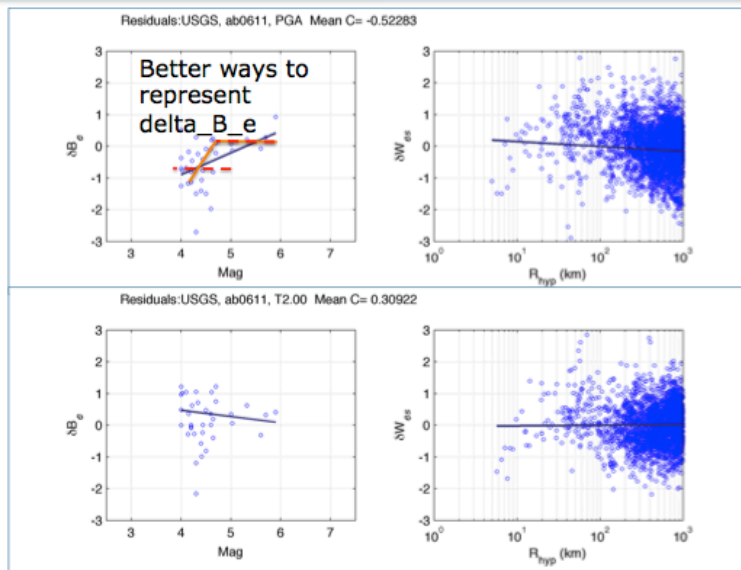

Mixed-effects residuals – example Frankel et al. 96

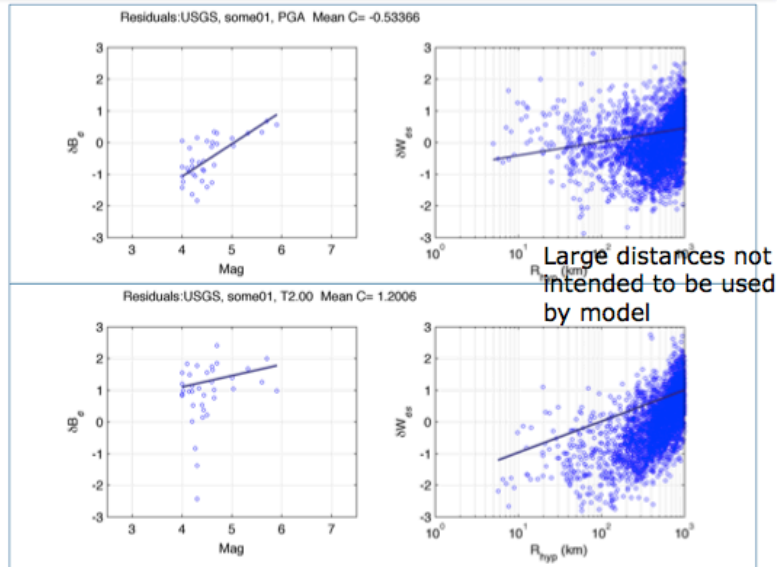

Total and Mixed effects residuals – example - Frankel et al. 96

Issue – trend in event terms Atkinson and Boore 06-11

Issue – trend in event terms Somerville et al. 01

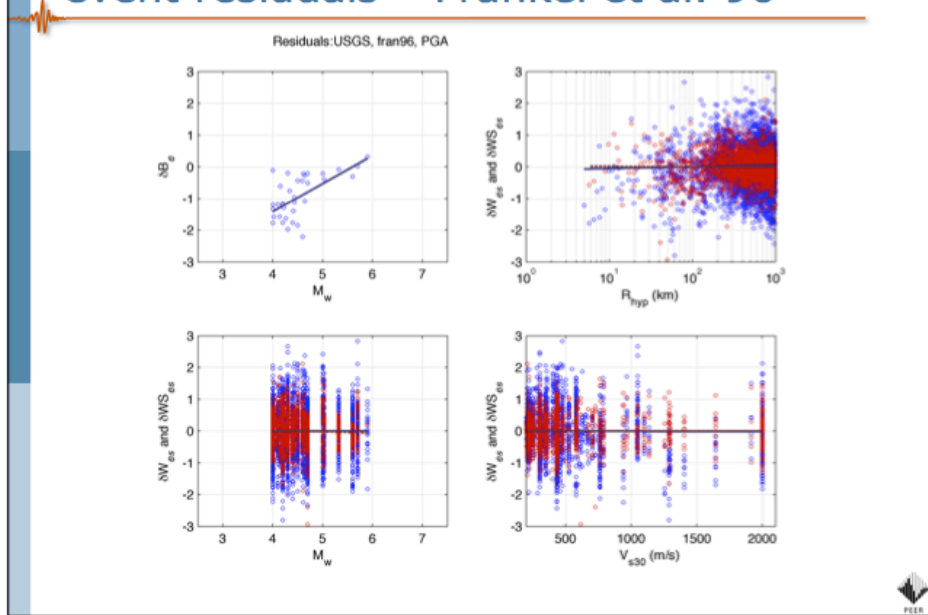

Accounting for repeatable site effects

- Only use stations with 5+ recordings
- Compute average within-event residuals to get site term at each station

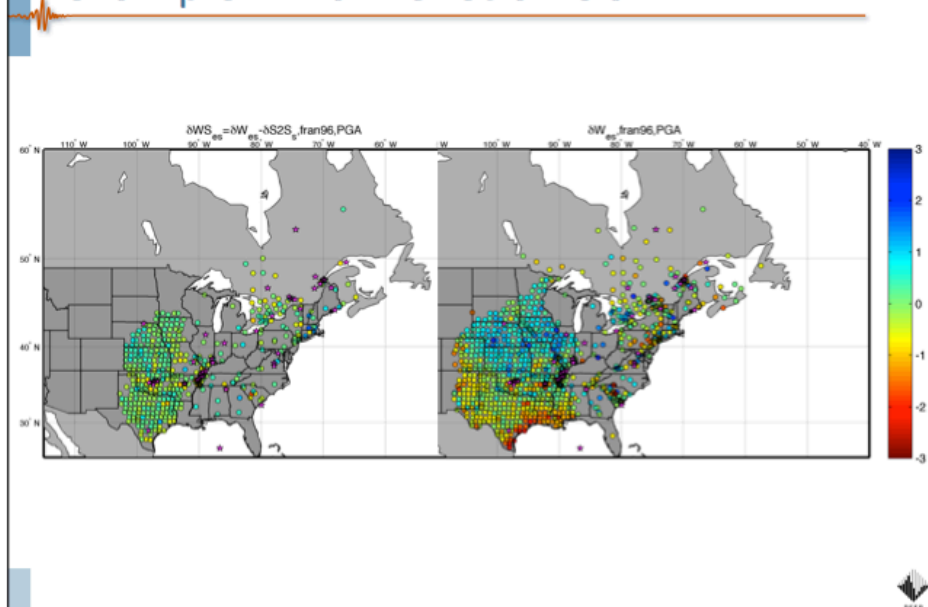

- Remove those site terms to get to site-corrected within-event residuals

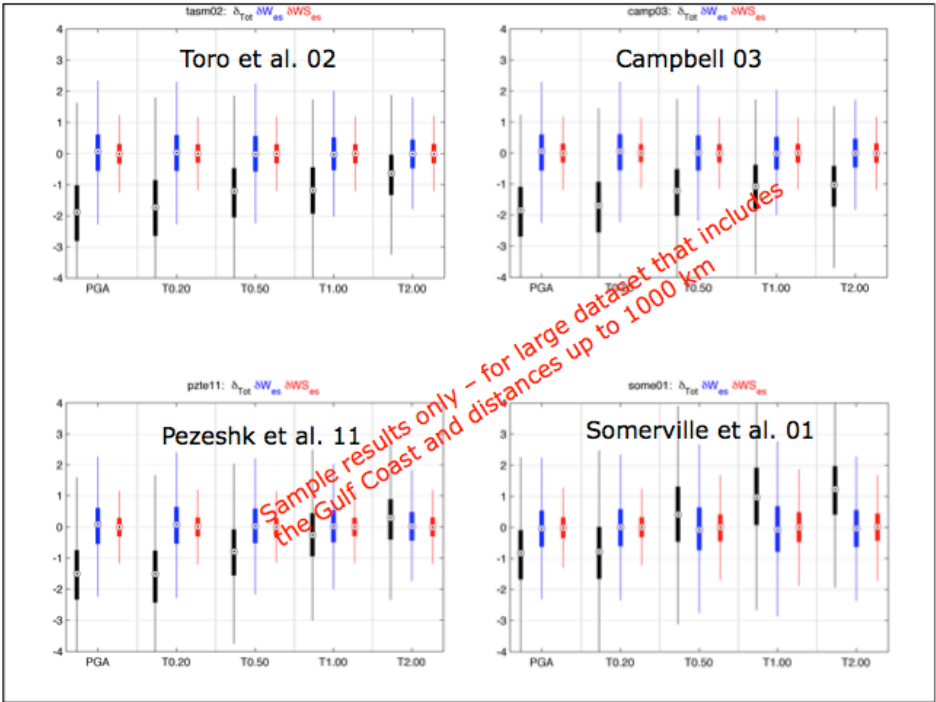

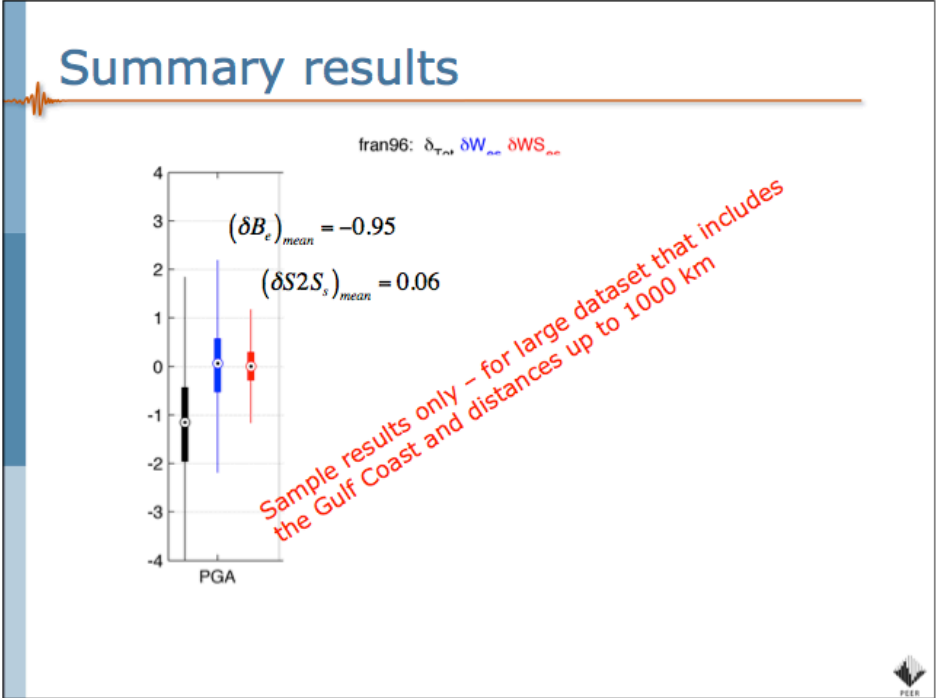

Within-event and site-corrected within-event residuals – Frankel et al. 96

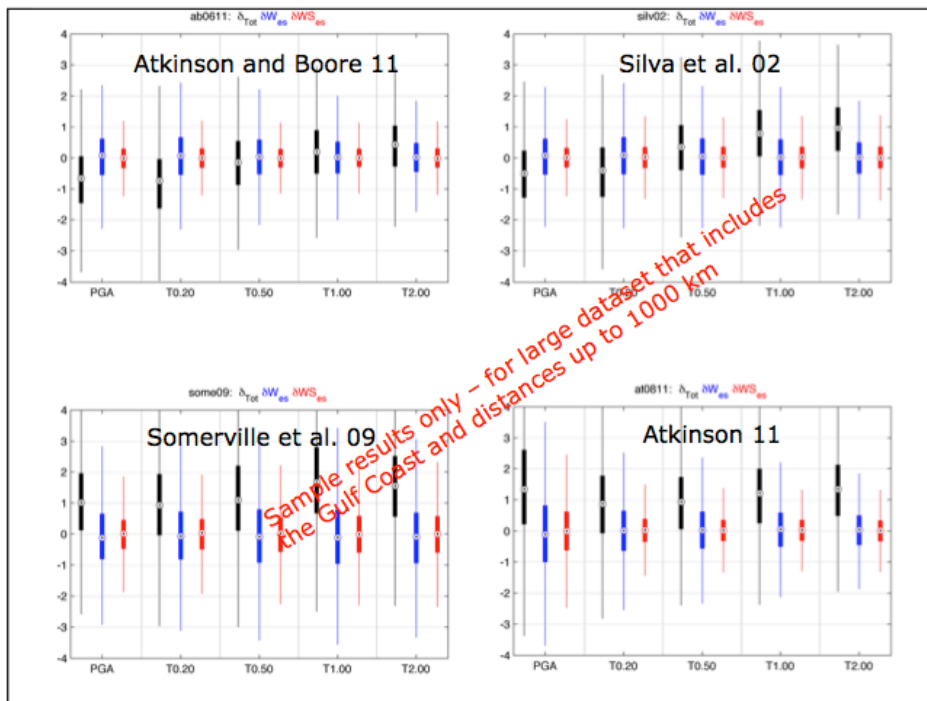

Total and Mixed effects residuals – example - Frankel et al. 96

Summary results

Looking at residuals – understanding GMPE fit to data

- Residuals analyses that account for mixed effects allow to remove potential bias from unevenly sampled datasets
- Further removing systematic site effects may be very useful in the assessment – especially for USGS where site conditions are fixed (BC boundary)
 - Currently, Vs30 poorly constrained in the CEUS
 - Site terms do not require knowledge of site conditions
- Binning of results (M, R, Vs30) may be a good approach

Looking at residuals – understanding GMPE fit to data

- Issue - what events/stations to keep?
 - Look at data on a per-event basis to understand attenuation fit and potential other data correlations.
 - What to do with “triggered” events (injection, other events)?
 - Regionalization?
- What site-correction factors to use?
 - We have site terms, no reliable site conditions
- Evaluation
 - Compare results between GMPEs
 - Assess slopes in residuals – favor GMPEs with smaller event term slopes, and overall centered trends
 - Careful not to extrapolate to larger M where there is no data to constrain the fit!!!

Vs30 map – measured+best estimates
